October 7, 2021

# The State of Affairs

Two people at a table, Pierre and Socrates, and a robot waiter.

# Formal Semantics

Its goal is to:

- Represent the state of affairs.
- Translate phrases or sentences such as *The robot brought the meal or the meal on the table* into logic formulas
- Solve references: Link words to real entities
- Reason about the world and the sentences.

A way to represent things and relations is to use first-order predicate calculus (FOPC) and predicate–argument structures

# Predicates

## Constants:

```
% The people:
  'Socrates'.
  'Pierre'.

% The chairs:
  chair1.      % chair #1
  chair2.      % chair #2

% The unique table:
  table1.      % table #1
```

## Predicates to encode properties:

```
person('Pierre').
person('Socrates').

object(table1).
object(chair1).
object(chair2).

chair(chair1).
chair(chair2).
table(table1).
```

## Predicates to encode relations:

```
in_front_of(chair1, table1).
on('Pierre', table1).
```

# Prolog

Prolog is a natural tool to do first-order predicate calculus

- Things, either real or abstract, are mapped onto constants – or atoms: 'Socrates', 'Pierre', chair1, chair2.
- Predicates can encode properties: `person('Pierre')`, `person('Socrates')`, `object(table1)`, `object(chair1)`.
- Predicates can encode relations: `in_front_of(chair1, table1)`, `on('Pierre', table1)`.
- Variables unify with objects

# Querying the State of Affairs

Constants:

```
?- table(chair1).  
false.  
?- chair(chair2).  
true.
```

Variables:

```
?- chair(X).  
X = chair1;  
X = chair2
```

Conjunctions:

```
?- chair(X), in_front_of(X, Y), table(Y).  
X = chair1, Y = table1
```

# Logical Forms

Logical forms map sentences onto predicate-argument structures

*I would like to book a late flight to Boston*

```
would_like_to(i,  
  book(i,  
    np_pp(a(late(flight)),  
      X^to(X, boston))))
```

# Compositionality

The principle of compositionality assumes that a sentence's meaning depends on the meaning its phrases

“The meaning of the whole is a function of the meaning of its parts.”

A complementary assumption is that phrases carrying meaning can be mapped onto constituents – syntactic units.

The principle of compositionality ties syntax and semantics together.

We saw that a predicate-argument structure could represent a sentence – the whole. How to represent the parts – the constituents?

# $\lambda$ -Calculus

The  $\lambda$ -calculus is a device to abstract properties or relations.

$$\lambda x. \text{property}(x)$$

or

$$\lambda y. \lambda x. \text{relation}(x, y)$$

A  $\lambda$ -expression is incomplete until a value has been given to it.  
Supplying such a value is called a  $\beta$ -reduction.

$$(\lambda x. \text{property}(x)) \text{entity\#1}$$

yields

$$\text{property}(\text{entity\#1})$$

In Prolog,  $X^{\sim}\text{property}(X)$  represents  $\lambda x. \text{property}(x)$

# Nouns

Proper nouns: *Mark, Nathalie, Ludwig*

Common nouns (properties): *lecturer, book*:

$$\lambda x. \text{lecturer}(x) \quad \lambda x. \text{lecturer}(x)(\text{Bill}) = \text{lecturer}(\text{Bill})$$

Adjectives

$$\lambda x. \text{big}(x) \quad \lambda x. \text{big}(x)(\text{Bill}) = \text{big}(\text{Bill})$$

Adjectives and nouns: *big table*

$$\lambda x. (\text{big}(x) \wedge \text{table}(x))$$

Noun compounds are difficult: *lecture room*

$$\lambda x. (\text{lecture}(x) \wedge \text{room}(x)) \quad ?? \text{ Wrong!}$$

A better form is:

$$\lambda x. (\text{modify}(x, \text{lecture}) \wedge \text{room}(x))$$

although not completely satisfying

# Verbs

Verbs of being are similar to adjectives or nouns

Intransitive verbs	$\lambda x.rushed(x)$ $\lambda x.rushed(x)(Bill) = rushed(Bill)$
Transitive verbs	$\lambda y.\lambda x.ordered(x,y)$ $\lambda y.\lambda x.called(x,y)$
Prepositions	$\lambda y.\lambda x.to(x,y)$

# Semantic Parsing

Converts sentences to first-order logic or predicate-argument structures

Example:

*Mr. Schmidt called Bill*

to

`called('Mr. Schmidt', 'Bill').`

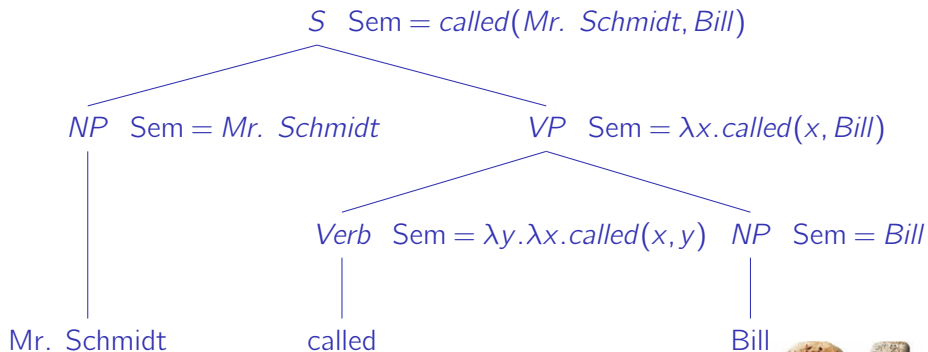

Assumption: We can compose sentence fragments (phrases) into logical forms while parsing

This corresponds to the compositionality principle

# Semantic Composition

Semantic composition can be viewed as a parse tree annotation

# RDF and SPARQL

RDF: A popular graph format to encode knowledge.

SPARQL: A query language for RDF

In many ways, very similar to Prolog.

```
ilppp:Pierre rdf:type ilppp:person.
```

```
ilppp:Socrates rdf:type ilppp:person.
```

```
ilppp:table1 rdf:type ilppp:object.
```

```
ilppp:chair1 rdf:type ilppp:object.
```

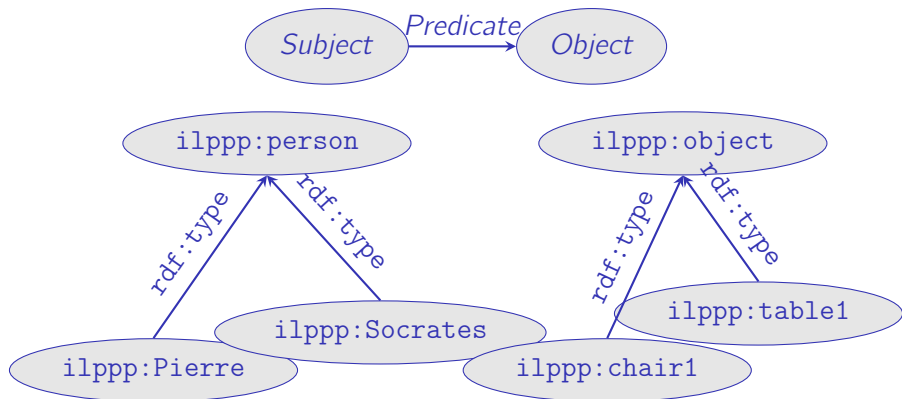

```
ilppp:chair2 rdf:type ilppp:object.
```

```
ilppp:chair1 ilppp:in_front_of ilppp:table1.
```

```
ilppp:Pierre ilppp:on ilppp:table1.
```

# RDF Triples

# RDF and SPARQL

Prolog:

```
?- object(X), object(Y), in_front_of(X, Y).  
X = chair1,  
Y = table1.
```

SPARQL:

```
SELECT ?x ?y  
WHERE  
{  
  ?x rdf:type ilppp:object.  
  ?y rdf:type ilppp:object.  
  ?x ilppp:in_front_of ?y  
}
```

Variables	?x	?y
Values	ilppp:chair1	ilppp:table1

# DBpedia, Yago, Wikidata, and Freebase

Graph databases consisting of billions of RDF triples.

Coming from a variety of sources such as Wikipedia infoboxes:

```
{{Infobox settlement
| official_name      = Busan Metropolitan City
...
| area_total_km2     = 767.35
...
| population_total   = 3,525,913
...
}}
```

DBpedia: The result of a systematic triple extraction from infoboxes

```
dbpedia:Busan foaf:name "Busan Metropolitan City"@en .
dbpedia:Busan dbo:populationTotal "3525913".
dbpedia:Busan dbo:areaTotal "7.6735E8" .
...
```

# SPARQL Endpoint

A network service accepting SPARQL queries such as:

```
prefix dbo: <http://dbpedia.org/ontology/>  
prefix foaf: <http://xmlns.com/foaf/0.1/>
```

```
SELECT ?entity ?population  
WHERE  
{  
  ?entity foaf:name "Busan Metropolitan City"@en.  
  ?entity dbo:populationTotal ?population.  
}
```

Address of the DBpedia endpoint: <http://dbpedia.org/sparql>

# Wikidata

Wikidata provides another endpoint based on Wikipedia data:

<https://query.wikidata.org>

```
query = '''  
SELECT ?entity ?population  
WHERE  
{  
  ?entity rdfs:label "Busan"@en .  
  ?entity wdt:P1082 ?population.  
}  
'''
```

```
url = 'https://query.wikidata.org/bigdata/namespace/wdq/sparql'  
data = requests.get(url, params={'query': prefixes + query, 'format': 'json'})
```

# DBpedia

The DBpedia query returns:

Variables	entity	population
Values	<a href="http://dbpedia.org/resource/Busan">http://dbpedia.org/resource/Busan</a>	3525913

where <http://dbpedia.org/resource/Busan> or `dbpedia:Busan` is a unique entity name based on the Wikipedia web addresses (URI nomenclature).

# Application: Spoken Language Translator (Agnäs et al. 1994)

English	<i>What is the earliest flight from Boston to Atlanta?</i>
French	<i>Quel est le premier vol Boston-Atlanta?</i>
English	<i>Show me the round trip tickets from Baltimore to Atlanta</i>
French	<i>Indiquez-moi les billets aller-retour Baltimore-Atlanta</i>
English	<i>I would like to go about nine am</i>
French	<i>Je voudrais aller aux environs de 9 heures</i>
English	<i>Show me the fares for Eastern Airlines flight one forty seven</i>
French	<i>Indiquez-moi les tarifs pour le vol Eastern Airlines cent quarante sept</i>

# Semantic Interpretation

Question:

*What is the earliest flight from Boston to Atlanta?*

Modeling a flight from Boston to Atlanta:

$$\exists x(\text{flight}(x) \wedge \text{from}(x, \text{Boston}) \wedge \text{to}(x, \text{Atlanta}) \wedge \exists y(\text{time}(y) \wedge \text{departs}(x, y)))$$

Finding the earliest flight:

$$\arg \min_y \exists x(\text{flight}(x) \wedge \text{from}(x, \text{Boston}) \wedge \text{to}(x, \text{Atlanta}) \wedge \exists y(\text{time}(y) \wedge \text{departs}(x, y)))$$

SLT uses the logical form as a universal representation, independent from the language.

It converts sentences from and to this representation

# Semantic Parsing

SLT does not use variables for the nouns.

*I would like to book a late flight to Boston*

is converted into the Prolog term:

```
would(like_to(i,  
    book(i,  
        np_pp(a(late(flight)),  
            X^to(X, boston))))))
```
