Chapter 5, part 2: Word Sequences

Pierre Nugues

Pierre.Nugues@cs.lth.se
http://cs.lth.se/pierre_nugues/

September 10, 2020

Word Sequences

Words have specific contexts of use.

Pairs of words like *strong* and *tea* or *powerful* and *computer* are not random associations.

Psychological linguistics tells us that it is difficult to make a difference between *writer* and *rider* without context

A listener will discard the improbable *rider of books* and prefer *writer of books*

A language model is the statistical estimate of a word sequence.

Originally developed for speech recognition

The language model component enables to predict the next word given a sequence of previous words: the writer of books, novels, poetry, etc. and not the writer of hooks, nobles, poultry, ...

N-Grams

The types are the distinct words of a text while the tokens are all the words or symbols.

The phrases from *Nineteen Eighty-Four War is peace*

Freedom is slavery Ignorance is strength

have 9 tokens and 7 types.
Unigrams are single words
Bigrams are sequences of two words
Trigrams are sequences of three words

Trigrams

Counting Bigrams With Unix Tools

- 1 tr -cs 'A-Za-z' '\n' < input_file > token_file
 Tokenize the input and create a file with the unigrams.
- tail +2 < token_file > next_token_file Create a second unigram file starting at the second word of the first tokenized file (+2).
- paste token_file next_token_file > bigrams Merge the lines (the tokens) pairwise. Each line of bigrams contains the words at index i and i+1 separated with a tabulation.
- And we count the bigrams as in the previous script.

Counting Bigrams in Python

```
bigrams = [tuple(words[inx:inx + 2])
           for inx in range(len(words) - 1)]
The rest of the count_bigrams function is nearly identical to
count_unigrams. As input, it uses the same list of words:
def count_bigrams(words):
    bigrams = [tuple(words[inx:inx + 2])
                for inx in range(len(words) - 1)]
    frequencies = {}
    for bigram in bigrams:
        if bigram in frequencies:
             frequencies[bigram] += 1
        else:
             frequencies[bigram] = 1
    return frequencies
```

Probabilistic Models of a Word Sequence

$$P(S) = P(w_1, ..., w_n),$$

= $P(w_1)P(w_2|w_1)P(w_3|w_1, w_2)...P(w_n|w_1, ..., w_{n-1}),$
= $\prod_{i=1}^{n} P(w_i|w_1, ..., w_{i-1}).$

The probability P(It was a bright cold day in April) from Nineteen Eighty-Four corresponds to

It to begin the sentence, then was knowing that we have It before, then a knowing that we have It was before, and so on until the end of the sentence.

$$P(S) = P(It) \times P(was|It) \times P(a|It, was) \times P(bright|It, was, a) \times P(April|It, was, a, bright, ..., in).$$

Approximations

Bigrams:

$$P(w_i|w_1, w_2, ..., w_{i-1}) \approx P(w_i|w_{i-1}),$$

Trigrams:

$$P(w_i|w_1, w_2, ..., w_{i-1}) \approx P(w_i|w_{i-2}, w_{i-1}).$$

Using a trigram language model, P(S) is approximated as:

$$P(S) \approx P(It) \times P(was|It) \times P(a|It, was) \times P(bright|was, a) \times ... \times P(April|day, in).$$

Maximum Likelihood Estimate

Bigrams:

$$P_{MLE}(w_i|w_{i-1}) = \frac{C(w_{i-1}, w_i)}{\sum\limits_{w} C(w_{i-1}, w)} = \frac{C(w_{i-1}, w_i)}{C(w_{i-1})}.$$

Trigrams:

$$P_{MLE}(w_i|w_{i-2},w_{i-1}) = \frac{C(w_{i-2},w_{i-1},w_i)}{C(w_{i-2},w_{i-1})}.$$

Conditional Probabilities

A common mistake in computing the conditional probability $P(w_i|w_{i-1})$ is to use

$$\frac{C(w_{i-1}, w_i)}{\#bigrams}.$$

This is not correct. This formula corresponds to $P(w_{i-1}, w_i)$. The correct estimation is

$$P_{MLE}(w_i|w_{i-1}) = \frac{C(w_{i-1},w_i)}{\sum\limits_{w} C(w_{i-1},w)} = \frac{C(w_{i-1},w_i)}{C(w_{i-1})}.$$

Proof:

$$P(w_1, w_2) = P(w_1)P(w_2|w_1) = \frac{C(w_1)}{\#words} \times \frac{C(w_1, w_2)}{C(w_1)} = \frac{C(w_1, w_2)}{\#words}$$

Training the Model

The model is trained on a part of the corpus: the **training set** It is tested on a different part: the **test set**

The vocabulary can be derived from the corpus, for instance the 20,000 most frequent words, or from a lexicon

It can be closed or open

A closed vocabulary does not accept any new word

An open vocabulary maps the new words, either in the training or test sets, to a specific symbol, <UNK>

Probability of a Sentence: Unigrams

Sparse Data

Methods:

Given a vocabulary of 20,000 types, the potential number of bigrams is $20,000^2 = 400,000,000$ With trigrams $20,000^3 = 8,000,000,000,000$

- Laplace: add one to all counts
 - Linear interpolation:

$$P_{DelInterpolation}(w_n|w_{n-2},w_{n-1}) = \lambda_1 P_{MLE}(w_n|w_{n-2}w_{n-1}) + \lambda_2 P_{MLE}(w_n|w_{n-1}) + \lambda_3 P_{MLE}(w_n)$$

- Good-Turing: The discount factor is variable and depends on the number of times a n-gram has occurred in the corpus.
- Back-off

Laplace's Rule

$$P_{Laplace}(w_{i+1}|w_i) = \frac{C(w_i, w_{i+1}) + 1}{\sum\limits_{w} (C(w_i, w) + 1)} = \frac{C(w_i, w_{i+1}) + 1}{C(w_i) + Card(V)},$$

Good-Turing

Laplace's rule shifts an enormous mass of probability to very unlikely bigrams. Good—Turing's estimation is more effective Let's denote N_c the number of n-grams that occurred exactly c times in the corpus.

 N_0 is the number of unseen n-grams, N_1 the number of n-grams seen once, N_2 the number of n-grams seen twice The frequency of n-grams occurring c times is re-estimated as:

$$c* = (c+1)\frac{E(N_{c+1})}{E(N_c)},$$

Unseen n-grams: $c* = \frac{N_1}{N_0}$ and N-grams seen once: $c* = \frac{2N_2}{N_1}$

Good-Turing for *Nineteen eighty-four*

Nineteen eighty-four contains 37,365 unique bigrams and 5,820 bigram seen twice.

Its vocabulary of 8,635 words generates $8635^2 = 74,563,225$ bigrams whose 74.513.701 are unseen.

New counts:

• Unseen bigrams:
$$\frac{37,365}{74,513,701} = 0.0005$$
.
• Unique bigrams: $2 \times \frac{5820}{37,365} = 0.31$.

• Unique bigrams:
$$2 \times \frac{5820}{37.365} = 0.31$$
.

Etc.

N_{c}	C*	Freq. of occ.	N_c	<i>C</i> *
74,513,701	0.0005	5	719	3.91
37,365	0.31	6	468	4.94
5,820	1.09	7	330	6.06
2,111	2.02	8	250	6 44
1,067	3.37	9	179	8 93
	74,513,701 37,365 5,820 2,111	74,513,701 0.0005 37,365 0.31 5,820 1.09 2,111 2.02	74,513,701 0.0005 5 37,365 0.31 6 5,820 1.09 7 2,111 2.02 8	74,513,701 0.0005 5 719 37,365 0.31 6 468 5,820 1.09 7 330 2,111 2.02 8 250

Backoff

If there is no bigram, then use unigrams:

$$P_{\mathsf{Backoff}}(w_i|w_{i-1}) = \begin{cases} \tilde{P}(w_i|w_{i-1}), & \text{if } C(w_{i-1},w_i) \neq 0, \\ \alpha P(w_i), & \text{otherwise.} \end{cases}$$

Simplified backoff:

$$P_{\text{Backoff}}(w_{i}|w_{i-1}) = \begin{cases} P_{\text{MLE}}(w_{i}|w_{i-1}) = \frac{C(w_{i-1}, w_{i})}{C(w_{i-1})}, & \text{if } C(w_{i-1}, w_{i}) \neq 0, \\ P_{\text{MLE}}(w_{i}) = \frac{C(w_{i})}{\# \text{words}}, & \text{otherwise.} \end{cases}$$

The sum of probabilities is not equal to one though.

Backoff: Example

w_{i-1}, w_i	$C(w_{i-1}, w_i)$		$C(w_i)$	$P_{Backoff}(w_i w_{i-1})$
<g>></g>			7072	_
<s> a</s>	133		2482	0.019

indeed already	0	backoff	64	0.00059
already being	0	backoff	80	0.00074
being transformed	0	backoff	1	$9.25 \ 10^{-6}$
transformed in	0	backoff	1759	0.016
in this	14		264	0.008
this way	3		122	0.011
way	18		7072	0.148

The figures we obtain are not probabilities. We can use the Good-Turing technique to discount the bigrams and then scale the unigram probabilities. This is the Katz backoff.

Quality of a Language Model (I)

The quality of a language model corresponds to its accuracy in predicting word sequences: $P(w_1, ..., w_n)$: The higher, the better.

We derive the model (the statistics) from a training set and evaluate this quality on a long unseen sequence sequence: The test set.

With the n-gram approximations, we have:

$$P(w_1, ..., w_n) = \prod_{i=1}^n P(w_i)$$
 Unigrams
$$P(w_1, ..., w_n) = P(w_1) \prod_{i=2}^n P(w_i | w_{i-1})$$
 Bigrams

$$P(w_1,...,w_n) = P(w_1)P(w_2|w_1)\prod_{i=3}^n P(w_i|w_{i-2},w_{i-1})$$
 Trigrams

etc.

Quality of a Language Model (II)

The probability value will depend on the length of the sequence. We take the geometric mean instead to standardize across different lengths:

$$\sqrt[n]{\prod_{i=1}^{n} P(w_i)}$$
 Unigrams $\sqrt[n]{P(w_1) \prod_{i=2}^{n} P(w_i|w_{i-1})}$ Bigrams

In practice, we use the log to compute the per word probability of a word sequence, the entropy rate:

$$H(L) = -\frac{1}{n}\log_2 P(w_1, ..., w_n).$$

Here the lower, the better

The figures are usually presented with the perplexity metric:

Mathematical Background

Entropy rate: $H_{rate} = -\frac{1}{n} \sum_{w_1,...,w_n \in L} p(w_1,...,w_n) \log_2 p(w_1,...,w_n)$. Cross entropy:

$$H(p, m) = -\frac{1}{n} \sum_{w_1,...,w_n \in L} p(w_1,...,w_n) \log_2 m(w_1,...,w_n).$$

We have:

$$H(p,m) = \lim_{n \to \infty} -\frac{1}{n} \sum_{w_1,...,w_n \in L} p(w_1,...,w_n) \log_2 m(w_1,...,w_n),$$

=
$$\lim_{n \to \infty} -\frac{1}{n} \log_2 m(w_1,...,w_n).$$

We compute the cross entropy on the complete word sequence of a test set, governed by p, using a bigram or trigram model, m, from set.

Other Statistical Formulas

• Mutual information (The strength of an association):

$$I(w_i, w_j) = \log_2 \frac{P(w_i, w_j)}{P(w_i)P(w_j)} \approx \log_2 \frac{N \cdot C(w_i, w_j)}{C(w_i)C(w_j)}.$$

• T-score (The confidence of an association):

$$t(w_i, w_j) = \frac{mean(P(w_i, w_j)) - mean(P(w_i))mean(P(w_j))}{\sqrt{\sigma^2(P(w_i, w_j)) + \sigma^2(P(w_i)P(w_j))}}$$

$$\approx \frac{C(w_i, w_j) - \frac{1}{N}C(w_i)C(w_j)}{\sqrt{C(w_i, w_j)}}.$$
